### Abstract:

Wounds disrupt the normal function and structure of the tissues, which are described as mechanical, thermal, or physical stressors that weaken the skin's epithelial health. Acute wounds that are caused by mechanical injuries, chemical damage, or burns usually recover in 8 to 12 weeks. Whereas, chronic wounds heal slowly and leave behind painful scars. They are frequently linked to underlying illnesses like diabetes, infections, and insufficient initial therapy. *Pyoderma gangrenosum*, diabetic foot ulcers, arterial ulcers, pressure ulcers, and venous ulcers are the most prevalent forms of chronic wounds. Through an examination of wound causes, classification, and typical topical preparations, this page seeks to give readers a thorough grasp of wounds.

**KEYWORDS:** *Wound, Topical ointment, Wound Healing, Mechanism of Action, injury*
