**Introduction**

This case highlights the role of perioperative dynamic ultrasonographic assessment of trachea and echocardiographic evaluation in a middle-aged patient scheduled for excision of pelvic leiomyosarcoma with extensive regional involvement. He had a known history of hyperthyroidism, large thyroid swelling, and severe mitral regurgitation (MR). Large thyroid swellings, whether accompanied by airway compromise or not, present a significant challenge for anesthesiologist, while when securing the airway. The presence of a thyroid swelling can result in the deviation or compression of the trachea. While static ultrasonographic evaluation is essential to protocolize the management approach, the conventional parameters may not always provide complete picture, therefore, dynamic assessment can prove invaluable in decision making on airway management. Moreover, echocardiographic assessment of MR during surgery helps to titer hemodynamic parameters, and to maintain adequate preload and afterload.
