INTRODUCTION

The erector spinae block is a technically easier block to administer using ultrasound guidance or using anatomical landmarks when compared to other regional blocks¹. Here we present the case of a 6-year-old child who presented with a vascular malformation in the right lateral chest wall. Although we have different methods of providing perioperative analgesia for thoracic procedures like central neuraxial blockades, paravertebral blocks or intercostal blocks, erector spinae block appears appealing due to its ease of administration and relative lack of complications².
